

Dark matter gravitational phased space distortion projection without the use of fermion & hadron particles.

Virtual equivalent in the space-time continuum:

$$\ln 4\pi = \frac{\text{neutron mass} - \text{proton mass}}{\text{electron mass}} \text{ equals } 2.531024247\dots$$

Actual gravitational phased space distortion with dark matter.

$$\text{Phase shift: } \phi_S = (\ln 4\pi + 3) \cdot \theta_0 = 5.53^\circ \text{ (constant)}$$

$$a_c = H_0 \cdot c = 2\pi \cdot \sqrt{e} \cdot G \cdot P_A^0 = 6.914 \times 10^{-10} \text{ m/s}^2, \text{ Universal acceleration of space}$$

$H_0$  = Hubble's constant

$P_A^0 = 1 \text{ kg/m}^2$ , Area density, this equals 1 kilogram per meter squared (constant).

$$\frac{a_c}{G \cdot P_A^0} = \frac{H_0 \cdot c}{G \cdot P_A^0} = \frac{\text{rad}}{\phi_s} = 2\pi \cdot \sqrt{e}$$

$$F_{V\Delta} = \frac{O_{VL} \cdot F_{LV}}{O_{VH}^2} \times \frac{1}{\sin(\text{rad} - 2\pi\sqrt{e})} = \frac{O_{VL} \cdot F_{LV}}{O_{VH}^2} \times \frac{1}{\sin\left(\left(\text{rad} - \frac{a_c}{G \cdot P_A^0}\right) \cdot \theta_0\right)}$$

$\theta_0$ , Equals an observation to collapse the wave function to particle values and is constant to one degree.

$G$  = Gravitational constant.

$G \cdot P_A^0$ : This is equivalent to the gravitational acceleration, with a value of mass of one kilogram per meter squared used as a reference point.

$F_{V\Delta}$  = This is a factored number. 1 equals 100 percent. Factor of the flat line velocity of 226 km per second.

$O_{VL}$  = Orbital velocity using conventional Newton's laws and light emitting stars in the galaxy. Sun = 160 km/s

$O_{VH}$  = Observed velocity which is higher than the calculated  $O_{VL}$  value. Sun = 220 km/s

$F_{LV}$  = Flat line velocity which is 226 km per second.

If  $O_{VL} > F_{LV}$  then the orbital path of a star is toward the center of the galaxy and not under the influence of "Dark Matter".

If  $O_{VL} < F_{LV}$  then the orbital path is under influence of "Dark Matter".
